 Abstract : The results of investigation are analyzed concerning the composition of "copper" scales in steam boilers that is, deposits of metallic copper with some additions of oxides of iron and conditions under which they form. Some ways are indicated to avert the depositing of copper on highly heated sections of the heating surface. To achieve this, the addition to the feed-water of ingredients which with the copper content form more stable complex compounds (polyamines, metaphosphates, etc.), is suggested. Charts.

TITLE: The content of sodium silicate and free silicic acid in super-heated steam of uniflow boilers at 110 atm. (Soderzhaniye silikata natriya i svobodnoy kremniyevoy kisloty b peregretoy pare pryamotoknykh kotlov pri 110 at)

PERIODICAL: "Teploenergetika" (Thermal Power), Vol.4, No.4, April, 1957, pp.37-40 (U.S.S.R.)

ABSTRACT: Available information about the content of free silicic acid and its compounds in superheated steam are incomplete and sometimes contradictory. Moreover, the special features of steam generation in uniflow boilers may influence the content of these substances in the steam. It was, therefore, decided to carry out rig tests, the results of which are given in this article. In the experimental set-up high pressure steam ( $p = 140$  atm,  $t = 450^\circ\text{C}$ ) was first directed into a special cooler in which it became slightly wet, and was then passed through a regulating valve into a separator which, besides removing the water removed most of the admixtures contained in the initial steam. From here the purified steam passed into a mixer in which sodium silicate or free silicic acid were added to it in known quantities. After the mixer the steam was passed to a heater which

The content of sodium silicate and free silicic acid in <sup>257</sup> super-heated steam of uniflow boilers at 110 atm. (Cont.)

imitated the transitional zone of a single pass boiler. The heating medium was steam at higher pressure. Beyond the heater the steam was passed to a condenser. The condensate was collected in measuring tanks. Samples were taken in stainless steel equipment and the  $\text{SiO}_3^{2-}$  - ion content was determined by the blue molybdenum complex on a photo-colorimeter. In some experiments the silicic acid content of the super-heated steam was determined both colorimetrically and gravimetrically and good agreement was obtained. Various precautions that were taken to ensure accuracy of measurement are described. The results of the experiments are presented in the form of graphs and the results of the determinations of the content of sodium silicate and free silicic acid carried out under conditions corresponding to the generation of steam in single pass boilers at a pressure of 110 atm and superheated steam temperatures up to approximately  $420 - 430^\circ\text{C}$  permit the following important practical conclusions to be drawn:

(1) If the feed water of a single pass boiler contains  $\text{Na}_2\text{SiO}_3$  in concentrations equal to or greater than 0.03 to 0.04 mg/kg of  $\text{SiO}_3^{2-}$ , the content of  $\text{SiO}_3^{2-}$  in the super heated steam (the temperature of which in

TITLE: Application of Ionites in Water-and Vapour-Analysis in Thermal Power Economy (Primeneniye ionitov pri analize vody i para v teplosilovom khozyaystve)

PERIODICAL: Zavodskaya Laboratoriya, 1957, Vol. 23, Nr 9, pp. 1060-1063 (USSR)

ABSTRACT: The quality control of water and steam in the modern thermal power economy requires application of methods with a sensitivity of the order of  $10^{-7}$  and even  $10^{-8}\%$ . The selective separation of cations and anions out of the water solutions by the aid of ionites makes it possible to give a satisfying answer to one part of this problem. Here a survey on the applied methods is given. The preparation of a water free from metal cations is obtained by filtering the ordinary distilled water through a column filled with a cation (which is carefully cleaned with hydrochloric acid). In order to obtain desalted water, a successive filtering through two or more columns is carried out. Some of these are filled with H-cationites, others with OH-anionites. The ionites are also used in the determination of the admixtures in the vapour and condensate. The ionites are applied for the complete analysis of the scale deposit and other sediments. There are 5 figures and 14 references, 13 of which are Slavic.

Title : Causes of Boiler Steam Contamination

Orig Pub : Elektr.stantsii, 1955, No 1, 6-9

Abstract : On summing-up the results of observations relative to the salt content (S) of boiler water and steam, the author arrives at the following conclusions: In uniflow boilers maximal content of substances in the steam is determined by their solubility therein. In natural circulation boilers it is necessary to differentiate steam contamination precritical and transcritical region. In the former (when S of steam increases little with increase of S of boiler water) the principal cause is intake of coarsely dispersed admixtures of boiler water,  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$ ,  $(\text{SiO}_2)_x$  etc., that accumulate at the steam-

TITLE: A phase analysis of external (ash) deposits. (Fazovyy analiz naruzhnykh otlozheniy)

PERIODICAL: Teploenergetika, 1958, No.7, pp. 82-84 (USSR)

ABSTRACT: Ash deposits formed in the tail heating surfaces of furnaces are mixtures of various compounds, many of which, such as sulphuric acid and sulphates of aluminium and trivalent iron, are corrosive to metals whilst others are products of corrosion. In analysing ash deposits these compounds are of particular interest: determinations are first made of free sulphuric acid and then of sulphates of  $Fe^{+3}$ ,  $Fe^{+2}$ , Al, Ca, Mg and Na. The authors determine the content of free sulphuric acid and sulphates of iron, aluminium, calcium and magnesium from the different solubilities of these substances in butanol, ethanol and water. Sulphuric acid is extracted with butanol, sulphates of trivalent iron and aluminium are extracted with ethanol in which the sulphates of bivalent iron, potassium magnesium and sodium are hardly soluble (see Table.1.). The analytical procedure is then described in more detail. The method is simple and reasonably accurate (see Tables 2. & 3.). It is most important to keep ash samples dry, particularly as some of the components are

Card 1/2

TITLE: The Determination of the Content of Free Sulfuric Acid in  
Boiler Deposits (Opredeleniye soderzhaniya svobodnoy sernoy  
kisloty v kotel'nykh otlozheniyakh)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol. 24, Nr 4, pp. 416-418 (USSR)

ABSTRACT: In the combustion of sulfurous fuels deposits are produced which contain free sulfuric acid as well as various sulfates. This leads to the corrosion of the metal surface thus giving rise to a quantitative determination of free sulfuric acid. A method was worked out in which free sulfuric acid is selectively extracted with butanol, in which case it must be avoided that the finely ground sample comes into contact with water during the investigation, because this might lead to a dissolution of the sulfates. The butanol extract is then titrated in the presence of methyl orange with a 0.1n lye solution. According to the weighed portion 0.08-0.04% of free sulfuric acid can be determined with an absolute accuracy of up to 0.1%, in which case no disturbance was observed with weighed portions of 0.5 - 5.0 g and extraction could be completed

TITLE: The Preparation of Distillate in an Installation with  
Direct-Flow Gas Evaporator (Prigotovleniye distillyata  
v ustanovke s pryamotochnym gazovym isparitelem)

PERIODICAL: Teploenergetika, 1959, Nr 3, pp 49-54 (USSR)

ABSTRACT: By the use of gas evaporators it is possible to obtain  
distillate in an amount up to 8-10% of the steam raising  
capacity of the boiler. In addition, the flue gas  
temperature is reduced, the size of the convective parts  
of the furnace is smaller and corrosion of the heating  
surfaces is reduced. Gas evaporators can operate either  
on a direct-flow circuit or with natural circulation.  
All the equipment used in the gas evaporators is proved  
and reliable. In October, 1954 a gas evaporator was  
added to a boiler of 160-200 tons/hour output. A small  
heat-exchanger coil was installed at the end of the  
existing convective part of the furnace beyond the air

Card 1/4

SOV/96-59-3-11/21

The Preparation of Distillate in an Installation with Direct-Flow Gas Evaporator

heater. It was intended to operate during the winter period as an economiser and during the summer period as a gas evaporator. A general schematic diagram of the equipment is given in Fig.1 and a sketch of the horizontal separator in Fig.2. Since the gas evaporator operates at low pressure, steam is only contaminated by dropwise carry-over of salts. An expression is given for the ratio of the quantity of salt in the distillate to that at the inlet to the separators. In conducting the tests, in order to accelerate and simplify the analyses of water salt content, solutions of phosphates and chlorides were specially added to the water reaching the evaporator. The results of 16 tests are given in Table 1. The thermal efficiency and general characteristics of the gas evaporator were determined from long-term operating experience. The main conditions for producing distillate of the necessary quality during the tests are given in Fig.3. It appears that at humidities of up to 45%, almost all of the moisture reaching the separator is removed. At higher humidities the efficiency of removal

Card 2/4

SOV/96-59-3-11/21

The Preparation of Distillate in an Installation with Direct-Flow Gas Evaporator

is less and a single separator does not suffice. Even the use of two film separators in series, although a considerable improvement, does not give distillate of the required quality. Distillate quality as a function of various operating conditions is plotted in Fig.4 and 5. To study the operation of the separator during possible periods of intermittent salt carry-over, thermo-couples were installed on the coils. Thereby pulsation and the uniformity of distribution of water on the coils were registered. The corresponding test results are given in Fig.6. An outline drawing of the calorifier with multi-stage separation appears in Fig.7 and the main characteristics of the equipment are stated. Operating experience showed a high thermal efficiency; the tubes did not become contaminated or damaged, except occasionally when they were abraded by ash. There were no special difficulties in erection or repair and the installation was particularly reliable in operation. Although in some cases the tubes operated below the dew point, external

Card 3/4

SOV/96-59-3-11/21

The Perparation of Distillate in an Installation with Direct-Flow  
Gas Evaporator

corrosion was not observed. After 13,000 hours operation one coil was cut out of the calorifier and no internal deposits were found. On the basis of this operating and test data extensive introduction of gas evaporators is recommended. Their field of application should be determined and design and operating instructions worked out. There are 7 figures, 2 tables and 2 Soviet references.

TITLE: Chemical Control at Thermal Power Stations.

PERIODICAL: Teploenergetika 1959, Nr 8, pp 3-6 (USSR)

ABSTRACT: The importance of chemical control work in power stations is increasing as a consequence of the increase in steam conditions and of the construction of district-heating power stations at which condensate losses may be very high. Power station chemists are also concerned with the analysis of fuel, flue gases and ash and other subjects. The information obtained is necessary to the chief engineer for the proper running of the power station. Improvements in chemical work are needed in respect of analytical methods, and simplification and automation of control. As the work develops it may be necessary to provide chemists only for a single shift instead of round the clock. The tendency has been to simplify control methods by extending the use of colorimetry, but calorimetric methods used in power station laboratories are not yet entirely satisfactory. It is necessary to develop new and simple photo-colorimeters, also simple

Card 1/3

SOV/96--59--8--1/27

Chemical Control at Thermal Power Stations

non-fading colour standards for visual colorimeters. Simpler test methods are needed, particularly for the determination of carbon dioxide in steam and condensate and also for pH value determinations. Automation is, of course, desirable but it should not be carried to extremes and the most important objectives are probably the monitoring of the following variables: oxygen in feed water, to control the operation of de-aerators; phosphates in boiler water, with a view to their automatic dosage; hardness of condensate, feed and make-up water, for the purpose of automatic control of hardness; salt content of steam, to operate a signalling device; and pH value, in order to control ammonia dosage. Research laboratories and organisations concerned with plant installation should develop new methods of studying scale formation, including low-temperature scale as well as the formation of other deposits and precipitates. Better

Card 2/3 methods are required for determining the concentration of

Chemical Control at Thermal Power Stations.

SOV/96-59-8-1/27

various ions in aqueous solutions. Although this work on chemical control is of undoubted importance the laboratories are as yet responding too slowly and on an inadequate scale.

Eds.: V. A. Golubev, S. M. Gurvich, Yu. M. Kostrikhin, and A. P. Mamet; Tech. Ed.: K. P. Voronin.

PURPOSE: This handbook is intended for chemists in the field of power engineering, personnel of laboratories, scientific research institutes, and planning and control organizations, as well as for students of universities and technical schools.

COVERAGE: This is the first of a three-volume handbook of chemistry in power engineering. It includes data on the water system of boilers, causes of corrosion and methods for controlling it. It also contains general reference material on measures and units, chemical compounds, water and solutions, solubility of substances in water and water vapor at various temperatures, electrochemistry, gases, specifications and prices for certain reagents and materials. The book includes tables, charts, and diagrams. No personalities are mentioned. There are 32 references: 30 Soviet, 10 English, 2 German, and 1 Swedish.

TITLE: On the Question of Volatility of Boric Acid

PERIODICAL: Zavodskaya laboratoriya, 1960, Vol 26, Nr 1, pp 60 - 61 (USSR)

ABSTRACT: In connection with a paper of Sh. K. Ashratova (Zavodskaya laboratoriya, 1960, Vol 26, Nr 1, pp 59-60) on the volatility of boric acid the data given by Ashratova were adequately checked. It proved to be superfluous to use a reflux condenser for determinations of boric acid, as was stated by Sh. K. Ashratova. However, boric acid is volatile in water vapor, was referred to by P. Tchijewski (Ref 1). When boiling boric acid solution this volatility amounts only to 0.16 - 0.20% relatively, and may be neglected under the given analysis conditions. The statements by Ashratova and Tchijewski are therefore not contradictory as, in the case of highly diluted boric acid solutions, the volatility of boric acid in water vapor has to be considered at any rate. There is 1 reference.

Title : Some Experimental Data on the Morphology of Periosteal  
Receptors

Orig Pub : Ortopediya, travmatol. i protezir., 1956, No 6, 139-140

Abstract : A study was made of the periosteum of long tubular bones in 59 dogs of different ages. More nerve endings were found in the zones of growth, especially near blood vessel branchings in the periosteum on the volar surface of forelimb bones and on metacarpals where continuous receptor zones were formed by the nerve endings. Medullated and nonmedullated nerve fibers, as well as encapsulated nerve endings, were predominant in the outer layer of the periosteum. Receptors of the inner layer were more

Card 1/2

S-3

Abs Jour : Ref Zhur - Biol., No 3, 1958, 12396

complex structures, having the appearance of bushes, loops, clublike thickenings, dicotomizing fibers, variously shaped arborizations, networks and tortuous lines. An intimate relationship between nerve endings and cellular elements of the inner layer of periosteum was observed. Nerve endings of this layer sometimes form the second receptor zone. Encapsulated nerve endings located around the vessels or in their walls belong to the category of angio- and chemoreceptors. Lability of the neuroreceptor apparatus, characterized by physiologic degeneration and intensive regeneration of nerve fibers in the periosteum, was noted.

Title : Experimental Data on Vascularization and Innervation in the Normal and in Some Pathologic Conditions (Preliminary Report).

Orig Pub : Vestn. khirurgii, 1956, 77, No. 2, 57-63

Abstract : The paths of large blood vessels and nerves and their interrelationships in the periosteum of long bones were studied. Neurovascular bundles with various complexities of branching were discovered. A difference in the vascularization of the periosteum of young animals (dense network) and adult dogs (sparse sinuous network) was noted.

Report on 34 patients, 6 of whom had concomitant injury of the nerve trunks. The best anatomical and functional results were obtained by skeletal traction. Other methods of treatment of these fractures should only be employed on special indications. Good approximation of the fragments and early movements of the joint aid in restoration of the function. Remote results in 21 patients who were followed up for 7 yr. were excellent in 16, good in 3 and poor in 2.
